

1. NAME OF THE MEDICINAL PRODUCT

GILENYA[®] 0.25 mg hard capsules
GILENYA[®] 0.5 mg hard capsules

2. QUALITATIVE AND QUANTITATIVE COMPOSITION

0.25 mg hard capsules: Each capsule contains 0.25 mg fingolimod (as hydrochloride).
0.5 mg hard capsules: Each capsule contains 0.5 mg fingolimod (as hydrochloride).

For the full list of excipients, see section 6.1.

3. PHARMACEUTICAL FORM

Hard capsule

0.5 mg capsule: White opaque (body) and bright yellow opaque (cap), size 3, with black radial imprint “FTY 0.5 mg” imprinted with yellow ink on cap and two radial bands, containing white to almost white powder.

0.25 mg capsule: Ivory opaque (body and cap), size 3, with black radial imprint “FTY 0.25 mg” on cap and black radial band on body containing white to almost white powder.

4. CLINICAL PARTICULARS

4.1 Therapeutic indications

Gilenya is indicated as monotherapy for the treatment of adult patients and paediatric patients of 10 years of age and above with the relapsing-remitting form of multiple sclerosis to reduce the frequency of clinical exacerbations and to delay the progression of physical disability.

4.2 Posology and method of administration

The treatment should be initiated and supervised by a physician experienced in multiple sclerosis.

Posology

In adults, the recommended dose of Gilenya is one 0.5 mg capsule taken orally once daily.

In paediatric patients (10 years of age and above), the recommended dose is dependent on body weight:

- *Paediatric patients with body weight ≤ 40 kg*: one 0.25 mg capsule daily taken orally.
- *Paediatric patients with body weight > 40 kg*: one 0.5 mg capsule daily taken orally.

Paediatric patients who start on 0.25 mg capsules and subsequently reach a stable body weight above 40 kg should be switched to 0.5 mg capsules.

Gilenya can be taken with or without food. If a dose is missed treatment should be continued with the next dose as planned.

When switching from a 0.25 mg to a 0.5 mg daily dose, it is recommended to repeat the observation after first dose.

For recommendations related to switching patients from other disease modifying therapies to Gilenya (see section 4.4).

Special populations

Elderly population

Gilenya should be used with caution in patients aged 65 years and over due to insufficient data on safety and efficacy (see section 5.2).

Renal impairment

Gilenya was not studied in patients with renal impairment in the multiple sclerosis pivotal studies. Based on clinical pharmacology studies, no dose adjustments are needed in patients with impairment.

Hepatic impairment

Gilenya must not be used in patients with severe hepatic impairment (Child-Pugh class C) (see section 4.3). Although no dose adjustments are needed in patients with mild or moderate hepatic impairment, caution should be exercised when initiating treatment in these patients (see sections 4.4 and 5.2).

Diabetic patients

Gilenya has not been studied in multiple sclerosis patients with concomitant diabetes mellitus. Gilenya should be used with caution in these patients due to a potential increase in the risk of macular oedema (see sections 4.4 and 4.8). Regular ophthalmological examinations should be conducted in these patients to detect macular oedema.

Paediatric population (below 10 years of age)

The safety and efficacy of Gilenya in paediatric patients below 10 years of age have not yet been studied.

4.3 Contraindications

Known immunodeficiency syndrome.

Patients with increased risk for opportunistic infections, including immunocompromised patients (including those currently receiving immunosuppressive therapies or those immunocompromised by prior therapies).

Severe active infections, active chronic infections (hepatitis, tuberculosis).

Known active malignancies, except for patients with cutaneous basal cell carcinoma.

Severe liver impairment (Child-Pugh class C).

Patients who in the last 6 months had myocardial infarction, unstable angina pectoris, stroke/transient ischemic attack, decompensated heart failure (requiring inpatient treatment), or New York Heart Association Class III/IV heart failure.

Patients who have concomitant treatment with Class Ia or Class III anti-arrhythmic drugs (see section 4.4).

Patients with second-degree Mobitz type II atrioventricular (AV) block or third-degree AV block, or sick-sinus syndrome, if they do not have a pacemaker (see section 4.4).

Patients with a baseline QTc interval ≥ 500 msec (see section 4.4).

Known hypersensitivity to fingolimod or to any of the excipients listed in section 6.1.

4.4 Special warnings and precautions for use

Bradycardia

Initiation of Gilenya treatment results in a transient decrease in heart rate and may also be associated with atrioventricular conduction delays, including the occurrence of isolated reports of transient, spontaneously resolving complete AV block (see sections 4.8 and 5.1).

After the first dose, the decline in heart rate starts within one hour and is steepest within 6 hours. The negative chronotropic effect of Gilenya persists beyond 6 hours and progressively attenuates over subsequent days of treatment. With continued administration, heart rate returns to baseline within one month. Conduction abnormalities were typically transient and asymptomatic. They usually did not require treatment and resolved within the first 24 hours on treatment. If necessary, the decrease in heart rate induced by fingolimod can be reversed by parenteral doses of atropine or isoprenaline.

All patients should have an ECG and blood pressure measurement performed prior to and 6 hours after the first dose of Gilenya. All patients should be monitored for a period of 6 hours for signs and symptoms of bradycardia with hourly heart rate and blood pressure measurement. Continuous (real time) ECG monitoring during this 6 hour period is recommended.

Should post-dose bradycardia-related symptoms occur, appropriate clinical management should be initiated and monitoring should be continued until the symptoms have resolved. Should a patient require pharmacological intervention during the first-dose observation period, overnight monitoring in a medical facility should be instituted and the first-dose monitoring should be repeated after the second dose of Gilenya.

The same precautions as for the first dose should be taken when patients are switched from the 0.25 mg to the 0.5 mg daily dose.

If the heart rate at 6 hours is the lowest since the first dose was administered (suggesting that the maximum pharmacodynamic effect on the heart may not yet be manifest), monitoring should be extended by at least 2 hours and until heart rate increases again. Additionally, if at 6 hours, the heart rate is <45 bpm in adults, <55 bpm in paediatric patients aged 12 years and above, or <60 bpm in paediatric patients aged 10 to below 12 years, or the ECG shows new onset second degree or higher grade AV block or a QTc interval ≥ 500 msec, extended monitoring (at least overnight monitoring), should be performed, and until the findings have resolved. The occurrence at any time of third degree AV block should also lead to extended monitoring (at least overnight monitoring).

Due to the risk of serious cardiac rhythm disturbances, Gilenya should not be used in patients with sinoatrial heart block, a history of symptomatic bradycardia or recurrent syncope. Since initiation of Gilenya treatment results in decreased heart rate and therefore a prolongation of the QT interval, Gilenya should not be used in patients with significant QT prolongation (QTc >470msec [adult females], QTc >460msec [paediatric females] or QTc >450msec [adult and paediatric males]) (see also section 4.3). Gilenya is best avoided in patients with relevant risk factors for QT prolongation, for example, hypokalaemia, hypomagnesaemia or congenital QT prolongation. Since significant bradycardia may be poorly tolerated in patients with history of cardiac arrest, uncontrolled hypertension or severe untreated sleep apnea, Gilenya should not be used in these patients (see also section 4.3). In such patients, treatment with Gilenya should be considered only if the anticipated benefits outweigh the potential risks. In patients for whom Gilenya is not contraindicated, if treatment is considered, advice from a cardiologist should be sought prior to initiation of treatment in order to determine the most appropriate monitoring strategy, at least overnight extended monitoring is recommended for treatment initiation (see also section 4.5).

Gilenya has not been studied in patients with arrhythmias requiring treatment with Class Ia (e.g. quinidine, disopyramide) or Class III (e.g. amiodarone, sotalol) antiarrhythmic medicinal products. Class Ia and Class III antiarrhythmic medicinal products have been associated with cases of torsades de pointes in patients with bradycardia (see section 4.3).

Experience with Gilenya is limited in patients receiving concurrent therapy with beta blockers, heart-rate-lowering calcium channel blockers (such as verapamil or diltiazem), or other substances that may decrease heart rate (e.g. ivabradine, digoxin, anticholinesteratic agents or pilocarpine). Since the initiation of Gilenya treatment is also associated with slowing of the heart rate (see also section 4.8, 'Bradycardia'), concomitant use of these substances during Gilenya initiation may be associated with severe bradycardia and heart block. Because of the potential additive effect on heart rate, treatment with Gilenya should not be initiated in patients who are concurrently treated with these substances (see also section 4.5). In such patients, treatment with Gilenya should be considered only if the anticipated benefits outweigh the potential risks. If treatment with Gilenya is considered, advice from a cardiologist should be sought regarding the switch to non-heart-rate lowering medicinal products prior to initiation of treatment. If the heart-rate-lowering medication cannot be stopped, cardiologist's advice should be sought to determine appropriate first dose monitoring, at least overnight extended monitoring is recommended (see also section 4.5).

If therapy is discontinued for more than 2 weeks after the first month of treatment, the effects on heart rate and atrioventricular conduction may recur on re-introduction of Gilenya treatment and the same precautions as for the first dose should apply. Within the first 2 weeks of treatment, first dose procedures are recommended after an interruption of one day or more. During weeks 3 and 4 of treatment first dose procedures are recommended after a treatment interruption of more than 7 days.

QT interval

In a thorough QT interval study of doses of 1.25 or 2.5 mg fingolimod at steady-state, when a negative chronotropic effect of fingolimod was still present, fingolimod treatment resulted in a prolongation of QTcI, with the upper limit of the 90% CI ≤ 13.0 ms. There is no dose- or exposure-response relationship of fingolimod and QTcI prolongation. There is no consistent signal of increased incidence of QTcI outliers, either absolute or change from baseline, associated with fingolimod treatment.

The clinical relevance of this finding is unknown. In the multiple sclerosis studies, clinically relevant effects on prolongation of the QTc-interval have not been observed but patients at risk for QT prolongation were not included in clinical studies.

Medicinal products that may prolong QTc interval are best avoided in patients with relevant risk factors, for example, hypokalaemia or congenital QT prolongation.

Immunosuppressive effects

Fingolimod has an immunosuppressive effect that predisposes patients to an infection risk, including opportunistic infections that can be fatal (see section 4.4, Infections), and may also increase the risk of developing certain malignancies (e.g., lymphoma, basal cell carcinoma, malignant melanoma; see section 4.4, Basal cell carcinoma and other cutaneous neoplasms; and section 4.8, Lymphomas). Physicians should carefully monitor patients, especially those with concurrent conditions or known factors, such as previous immunosuppressive therapy. If this risk is suspected, discontinuation of treatment should be considered by the physician on a case-by-case basis.

Infections

A core pharmacodynamic effect of Gilenya is a dose-dependent reduction of the peripheral lymphocyte count to 20-30% of baseline values. This is due to the reversible sequestration of lymphocytes in lymphoid tissues (see section 5.1).

Before initiating treatment with Gilenya, a recent complete blood count (CBC) (i.e. within 6 months) should be available. Assessments of CBC are also recommended periodically during treatment, and in case of signs of infection. Absolute lymphocyte count $< 0.2 \times 10^9/l$, if confirmed, should lead to treatment interruption until recovery, because in clinical studies, fingolimod treatment was interrupted in patients with absolute lymphocyte count $< 0.2 \times 10^9/l$.

Initiation of treatment with Gilenya should be delayed in patients with severe active infection until resolution.

Cases of progressive multifocal leukoencephalopathy (PML) have been reported in the post-marketing setting (see section 4.8). PML is an opportunistic infection caused by JC virus, which may be fatal or result in severe disability. Cases of PML have occurred after approximately 2-3 years of treatment. Although the estimated risk appears to increase with cumulative exposure over time, an exact relationship with the duration of treatment is unknown. The incidence rate for PML appears to be higher for patients in Japan; the reasons are currently unknown. Additional PML cases have occurred in patients who had been treated previously with natalizumab, which has a known association with PML. During routine MRI (in accordance with national and local recommendations), physicians should be vigilant for clinical symptoms or MRI findings that may be suggestive of PML. If PML is suspected, Gilenya treatment should be suspended until PML has been excluded. MRI findings suggestive of PML may be apparent before clinical signs or symptoms. Cases of PML, diagnosed based on MRI findings and the detection of JCV DNA in the cerebrospinal fluid in the absence of clinical signs or symptoms specific to PML, have been reported in patients treated with MS medications associated with PML, including Gilenya.

Cases of cryptococcal meningitis have been reported in the post-marketing setting after approximately 2-3 years of treatment, although an exact relationship with the duration of treatment is unknown (see section Undesirable effects). Cryptococcal meningitis may be fatal. For this reason, patients with symptoms and signs consistent with cryptococcal meningitis should undergo prompt diagnostic evaluation. If cryptococcal meningitis is diagnosed, appropriate treatment should be initiated.

Patients need to be assessed for their immunity to varicella (chickenpox) prior to Gilenya treatment. It is recommended that patients without a health care professional confirmed history of chickenpox or documentation of a full course of vaccination with varicella vaccine undergo antibody testing to varicella zoster virus (VZV) before initiating Gilenya therapy. A full course of vaccination for antibody-negative patients with varicella vaccine is recommended prior to commencing treatment with Gilenya (see section 4.8). Initiation of treatment with Gilenya should be postponed for 1 month to allow full effect of vaccination to occur.

Human papilloma virus (HPV) infection, including papilloma, dysplasia, warts and HPV-related cancer, has been reported under treatment with Gilenya in the post-marketing setting (see section 4.8). Due to the immunosuppressive properties of fingolimod, vaccination against HPV should be considered prior to treatment initiation with Gilenya taking into account vaccination recommendations. Cancer screening, including Pap test, is recommended as per standard of care.

Anti-neoplastic, immune-modulating or immunosuppressive therapies should not be co-administered due to the risk of additive immune system effects. For the same reason, corticosteroids should be co-administered with caution. Specific decisions as to the dosage and duration of treatment with corticosteroids should be based on clinical judgment. Co-administration of a short course of corticosteroids (up to 5 days as per study protocols) did not increase the overall rate of infection in patients treated with fingolimod in the Phase III clinical trials, compared to placebo.

The immune system effects of Gilenya may increase the risk of infections, including opportunistic infections (see section 4.8). Before initiating treatment with Gilenya, a recent complete blood count (CBC) (i.e. within 6 months or after discontinuation of prior therapy) should be available.

Initiation of treatment with Gilenya should be delayed in patients with severe active infection until resolution. Effective diagnostic and therapeutic strategies should be employed in patients with symptoms of infection while on therapy. During treatment, patients receiving Gilenya should be instructed to report symptoms of infection to their physician.

Suspension of treatment with Gilenya should be considered if a patient develops a serious infection and consideration of benefit-risk should be undertaken prior to re-initiation of therapy.

Elimination of fingolimod following discontinuation of therapy may take up to two months and vigilance for infection should therefore be continued throughout this period. Patients should be instructed to report symptoms of infection up to 2 months after discontinuation of fingolimod.

Macular edema

Macular edema with or without visual symptoms has been reported in 0.4% of patients treated with fingolimod 0.5 mg, occurring predominantly in the first 3-4 months of therapy (see section 4.8). An ophthalmic evaluation is therefore recommended 3-4 months after treatment initiation. If patients report visual disturbances at any time while on therapy, an evaluation of the fundus, including the macula, should be carried out.

Patients with a history of uveitis and patients with diabetes mellitus are at increased risk of macular oedema (see section 4.8). Gilenya has not been studied in multiple sclerosis patients with concomitant diabetes mellitus. It is recommended that multiple sclerosis patients with diabetes mellitus or a history of uveitis undergo an ophthalmic evaluation prior to initiating therapy and have follow-up evaluations while receiving therapy.

Continuation of Gilenya in patients with macular oedema has not been evaluated. It is recommended that Gilenya be discontinued if a patient develops macular oedema. A decision on whether or not Gilenya therapy should be re-initiated after resolution of macular oedema needs to take into account the potential benefits and risks for the individual patient.

Liver function

Increased hepatic enzymes, mostly alanine aminotransaminase (ALT) elevation, have been reported in multiple sclerosis patients treated with Gilenya. In clinical trials, a 3-fold the upper limit of normal (ULN) or greater elevation in ALT occurred in 8.0% of adult patients treated with fingolimod 0.5 mg compared to 2% of placebo patients. Elevations 5-fold the ULN occurred in 2% of patients on Gilenya 0.5 mg and 1% of patients on placebo. In clinical trials, Gilenya was discontinued if the elevation exceeded 5 times the ULN. Recurrence of liver transaminase elevations occurred with rechallenge in some patients, supporting a relationship to fingolimod. In clinical studies, transaminase elevations occurred at any time during treatment although the majority occurred within the first 12 months. Serum transaminase levels returned to normal within approximately 2 months after discontinuation of fingolimod.

Gilenya has not been studied in patients with severe pre-existing hepatic injury (Child-Pugh class C) and should not be used in these patients (see section 4.3).

Due to the immunosuppressive properties of fingolimod, initiation of treatment should be delayed in patients with active viral hepatitis until resolution.

Recent (i.e. within last 6 months) transaminase and bilirubin levels should be available before initiation of treatment with Gilenya. In the absence of clinical symptoms, liver transaminases should be monitored at Months 1, 3, 6, 9 and 12 on therapy and periodically thereafter. If liver transaminases rise above 5 times the ULN, more frequent monitoring should be instituted, including serum bilirubin and alkaline phosphatase (ALP) measurement. With repeated confirmation of liver transaminases above 5 times the ULN, treatment with Gilenya should be interrupted and only re-commenced once liver transaminase values have normalised.

Patients who develop symptoms suggestive of hepatic dysfunction, such as unexplained nausea, vomiting, abdominal pain, fatigue, anorexia, or jaundice and/or dark urine, should have liver enzymes checked and Gilenya should be discontinued if significant liver injury is confirmed (for example liver transaminase levels greater than 5-fold the ULN and/or serum bilirubin elevations). Resumption of therapy will be dependent on whether or not another cause of liver injury is determined and on the benefits to patient of resuming therapy versus the risks of recurrence of liver dysfunction.

Although there are no data to establish that patients with pre-existing liver disease are at increased risk of developing elevated liver function test (LFT) values when taking Gilenya, caution should be exercised when using Gilenya in patients with a history of significant liver disease.

Posterior reversible encephalopathy syndrome

Rare cases of posterior reversible encephalopathy syndrome (PRES) have been reported in adults at

0.5 mg dose in clinical trials and in the post-marketing setting (see section 4.8). Symptoms reported included sudden onset of severe headache, nausea, vomiting, altered mental status, visual disturbances and seizure. Symptoms of PRES are usually reversible but may evolve into ischemic stroke or cerebral hemorrhage. Delay in diagnosis and treatment may lead to permanent neurological sequelae. If PRES is suspected, Gilenya should be discontinued.

Interference with serological testing

Since fingolimod reduces blood lymphocyte counts via re-distribution in secondary lymphoid organs, peripheral blood lymphocyte counts cannot be utilised to evaluate the lymphocyte subset status of a patient treated with Gilenya. Laboratory tests involving the use of circulating mononuclear cells require larger blood volumes due to reduction in the number of circulating lymphocytes.

Blood pressure effects

Patients with hypertension uncontrolled by medication were excluded from participation in premarketing clinical trials and special care is indicated if patients with uncontrolled hypertension are treated with Gilenya.

In MS clinical trials, patients treated with fingolimod 0.5 mg had an average increase of approximately 3 mmHg in systolic pressure, and approximately 1 mmHg in diastolic pressure, first detected approximately 1 month after treatment initiation, and persisting with continued treatment. In the two- year placebo-controlled study, hypertension was reported as an adverse event in 6.1% of patients on fingolimod 0.5 mg and in 3.8% of patients on placebo. Therefore, blood pressure should be regularly monitored during treatment with Gilenya.

Respiratory effects

Minor dose-dependent reductions in values for forced expiratory volume (FEV₁) and diffusion capacity for carbon monoxide (DLCO) were observed with Gilenya treatment starting at Month 1 and remaining stable thereafter. Gilenya should be used with caution in patients with severe respiratory disease, pulmonary fibrosis and chronic obstructive pulmonary disease (see also section 4.8).

Prior treatment with immunosuppressives or immune-modulating therapies

When switching from other disease modifying therapies, the elimination half-life and mode of action of the other therapy must be considered in order to avoid an additive immune effect whilst at the same time minimizing risk of disease reactivation. Before initiating treatment with Gilenya, a recent CBC (i.e. after discontinuation of prior therapy) should be available to ensure any immune effects of such therapies (e.g. cytopenia) have resolved.

Beta interferon, or glatiramer acetate

Gilenya can generally be started immediately after discontinuation of beta interferon, or glatiramer acetate.

Natalizumab

Due to the long elimination half-life of natalizumab, caution regarding potential additive immune effects is required when switching patients from natalizumab to Gilenya. A careful case-by-case assessment regarding the timing of the initiation of Gilenya treatment is recommended. Elimination of natalizumab usually takes up to 2-3 months following discontinuation.

Malignancies

Cutaneous Malignancies

Basal cell carcinoma (BCC) and other cutaneous neoplasms, including malignant melanoma, squamous cell carcinoma, Kaposi's sarcoma and Merkel cell carcinoma, have been reported in patients receiving Gilenya (see section 4.8). Periodic skin examination is recommended for all patients, particularly those with risk factors for skin cancer. Since there is a potential risk of malignant skin growths, patients treated with Gilenya should be cautioned against exposure to sunlight without protection. Vigilance for skin lesions is warranted and a medical evaluation of the skin is recommended at initiation, and then every 6 to 12 months taking into consideration clinical judgement. The patient should be referred to a dermatologist in case suspicious lesions are detected.

Since there is a potential risk of malignant skin growths, patients treated with fingolimod should be cautioned against exposure to sunlight without protection. These patients should not receive concomitant phototherapy with UV-B-radiation or PUVA-photochemotherapy.

Lymphomas

There have been cases of lymphoma in clinical studies and the post-marketing setting. The cases reported were heterogeneous in nature, mainly Non-Hodgkin's Lymphoma, including B-cell and T-cell lymphomas. Cases of cutaneous T cell lymphoma (mycosis fungoides) have been observed (see section 4.8).

Return of disease activity (rebound) after Gilenya discontinuation

Cases of severe exacerbation of disease have been reported after stopping Gilenya in the post-marketing setting. This was generally observed within 12 weeks after stopping Gilenya, but was also reported up to and beyond 24 weeks after Gilenya discontinuation. Therefore, caution is indicated when stopping Gilenya therapy. If discontinuation of Gilenya is deemed necessary, patients should be monitored for relevant signs and symptoms and appropriate treatment should be initiated as required.

Tumefactive lesions

Rare cases of tumefactive lesions associated with MS relapse were reported in the post-marketing setting. In case of severe relapses, MRI should be performed to exclude tumefactive lesions. Discontinuation of Gilenya should be considered by the physician on a case-by-case basis taking into account individual benefits and risks.

Stopping therapy

If a decision is made to stop treatment with Gilenya a 6 week interval without therapy is needed, based on half-life, to clear fingolimod from the circulation (see section 5.2). Lymphocyte counts progressively return to the normal range within 1-2 months of stopping therapy (see section 5.1). Starting other therapies during this interval will result in concomitant exposure to fingolimod. Use of immunosuppressants soon after the discontinuation of Gilenya may lead to an additive effect on the immune system and caution is therefore indicated.

See also section above: Return of disease activity (rebound) after Gilenya discontinuation. Special

populations

Paediatric patients (10 years of age and above)

It is recommended that paediatric patients complete all immunizations in accordance with current immunization guidelines prior to initiating Gilenya therapy.

Pregnancy, fetal risk and contraception

Due to the potential for a serious risk to the fetus, the pregnancy status of females of reproductive potential should be verified prior to starting treatment with Gilenya. Medical advice should be given regarding the risk of harmful effects of the fetus associated with treatment.

While on treatment with Gilenya, females should not become pregnant and effective contraception is recommended during treatment and for 2 months after stopping treatment. If a female becomes pregnant while taking Gilenya, discontinuation of Gilenya should be considered, taking into account the individual benefit risk assessment for both the mother and the fetus. See section 4.6 and also section above: Return of disease activity (rebound) after Gilenya discontinuation.

4.5 Interaction with other medicinal products and other forms of interaction

Anti-neoplastic, immune-modulating or immunosuppressive therapies

Anti-neoplastic, immune-modulating or immunosuppressive therapies should not be co-administered due to the risk of additive immune system effects (see sections 4.3 and 4.4). For the same reason, corticosteroids should be co-administered with caution. Specific decisions as to the dosage and duration of concomitant treatment with corticosteroids should be based on clinical judgment.

Co-administration of a short course of corticosteroids (up to 5 days as per study protocols) did not increase the overall rate of infection in patients treated with fingolimod in the Phase III clinical trials, compared to placebo (see sections 4.4 and 4.8).

Caution should also be applied when switching patients from long-acting therapies with immune effects such as natalizumab or mitoxantrone (see section 4.4: Prior treatment with immunosuppressive or immune-modulating therapies).

Vaccination

During and for up to two months after treatment with Gilenya vaccination may be less effective. The use of live attenuated vaccines may carry a risk of infections and should therefore also be avoided during Gilenya treatment and for up to 2 months after treatment with Gilenya.

For paediatric patients, please also refer to subsection 'Paediatric patients (10 years of age and above)'.

Bradycardia-inducing substances

Fingolimod has been studied in combination with atenolol and diltiazem. When fingolimod was used with atenolol in an interaction study in healthy volunteers, there was an additional 15% reduction heart rate at fingolimod treatment initiation, an effect not seen with diltiazem. Treatment with Gilenya should not be initiated in patients receiving beta blockers, or other substances which may decrease heart rate, such as Class Ia and III antiarrhythmics, calcium channel blockers (such as verapamil or diltiazem), or other substances which may decrease heart rate (e.g. ivabradine or digoxin), anticholinesteratic agents or pilocarpine because of the potential additive effects on heart rate (see sections 4.4 and 4.8). If treatment with Gilenya is considered in such patients, advice from a cardiologist should be sought regarding the switch to non-heart-rate lowering medicinal products or appropriate monitoring for treatment initiation, at least overnight monitoring is recommended, if the heart-rate-lowering medication cannot be stopped.

Pharmacokinetic interactions of other substances on fingolimod

Fingolimod is primarily cleared *via* cytochrome CYP450 4F2 (CYP4F2) and possibly other CYP4F isoenzymes. Other enzymes like CYP3A4 may also contribute to its metabolism. Co-administration of fingolimod with ketoconazole resulted in a 1.7-fold increase in fingolimod and fingolimod phosphate exposure (AUC). Caution should be exercised with substances that may inhibit CYP3A4 (protease inhibitors, azole antifungals, some macrolides such as clarithromycin or telithromycin).

Pharmacokinetic interactions of fingolimod on other substances

Fingolimod is unlikely to interact with substances mainly cleared by the CYP450 enzymes or by substrates of the main transporter proteins.

Co-administration of fingolimod with ciclosporin did not elicit any change in the ciclosporin or fingolimod exposure. Therefore, fingolimod is not expected to alter the pharmacokinetics of medicinal products that are CYP3A4 substrates. Potent inhibitors of transporter proteins are not

expected to influence fingolimod disposition.

Co-administration of fingolimod 0.5 mg with oral contraceptives (ethinylestradiol and levonorgestrel) did not elicit any change in oral contraceptive exposure. Fingolimod and fingolimod-phosphate exposure were consistent with those from previous studies. No interaction studies have been performed with oral contraceptives containing other progestagens, however an effect of fingolimod on their exposure is not expected.

The co-administration of carbamazepine 600 mg twice daily at steady-state and a single dose of fingolimod 2 mg had a weak effect on the AUC of fingolimod and fingolimod-phosphate, decreasing both by approximately 40%. The clinical relevance of this decrease is unknown.

It is not known whether the concomitant administration of strong CYP450 inducers may decrease the exposure to fingolimod and fingolimod P.

4.6 Pregnancy, lactation, females and males of reproductive potential

Pregnancy

Before initiation of treatment in females of childbearing potential a negative pregnancy test result needs to be available. While on treatment, females should not become pregnant and active contraception is recommended. If a female becomes pregnant while taking Gilenya, discontinuation of Gilenya is recommended.

Risk summary

There are no adequate and well-controlled studies in pregnant females.

Available human data (post-marketing data and pregnancy registry information) suggest that use of Gilenya is associated with an increased prevalence of major congenital malformation in comparison to the general population.

While on treatment, females should not become pregnant and effective contraception is recommended. If a female becomes pregnant while taking Gilenya, discontinuation of Gilenya should be considered, taking into account the individual benefit risk assessment for both the mother and the fetus.

Medical advice should be given regarding the risk of harmful effects on the fetus associated with treatment and medical follow-up examination should be performed (e.g. ultrasonography examination). Also, the possibility of severe exacerbation of disease should be considered in females discontinuing Gilenya because of pregnancy or planned pregnancy, and patients should consult their physicians on potential alternatives (see section 4.4).

Reproductive studies in rats have demonstrated that Gilenya induced teratogenicity starting at a dose corresponding to 2 times the

exposure in humans at the recommended dose of 0.5 mg. Animal studies have shown reproductive toxicity including fetal loss and organ defects, notably persistent truncus arteriosus and ventricular septal defect. Furthermore, the receptor affected by fingolimod (sphingosine-1-phosphate receptor) is known to be involved in vascular formation during embryogenesis.

Studies from USA, Canada, major EU countries and South American countries have shown that the risk of birth defects in multiple sclerosis (MS) population is similar to that in the general population. For spontaneous abortions and still births, the background risk in the MS population in the US appears to be similar to that in the general US population.

Clinical considerations

If Gilenya is discontinued because of pregnancy or planned pregnancy see section 4.4 Special warnings and precautions for use - Return of disease activity (rebound) after Gilenya discontinuation and stopping therapy. For females planning to become pregnant, Gilenya should be stopped 2 months before conception.

Labour and delivery

There are no data on the effects of fingolimod on labour and delivery.

Human data

In more than 600 prospective pregnancies with live births, still births or termination of pregnancy due to fetal anomaly with maternal exposure to fingolimod during pregnancy that were reported in post-marketing setting, the proportion of major congenital malformations was approximately 5%. The prevalence of major congenital malformation in the general population is 2 to 4%.

The pattern of malformation reported for Gilenya is similar to that observed in the general population, wherein the common major malformations are:

- Congenital heart disease such as atrial and ventricular septal defects, tetralogy of Fallot
- Renal abnormalities
- Musculoskeletal abnormalities

There is no evidence of clustering of specific birth defects with Gilenya.

Animal data

Fingolimod was teratogenic in rats when given at doses of 0.1 mg/kg or higher. A dose of 0.1 mg/kg in rats corresponds to 2 times the exposure in humans at the recommended dose of 0.5 mg. The most common fetal visceral malformations included persistent truncus arteriosus and ventricular septum defect. An increase in post-implantation loss was observed in rats at 1 mg/kg and higher and a decrease in viable fetuses at 3 mg/kg. Fingolimod was not teratogenic in rabbits, however an increased embryo-fetal mortality was seen at doses of 1.5 mg/kg and higher, and a decrease in viable fetuses as well as fetal growth retardation at 5 mg/kg. A dose of 1.5 mg/kg in rabbits corresponds to similar exposure in humans at the recommended dose of 0.5 mg.

Available data do not suggest that Gilenya would be associated with an increased risk of male-mediated fetal toxicity.

In rats, F1 generation pup survival was decreased in the early postpartum period at doses that did not cause maternal toxicity. However, F1 body weights, development, behavior, and fertility were not affected by treatment with fingolimod.

Lactation

Risk summary

Fingolimod is transferred into the milk of treated animals during lactation at concentrations 2-3-fold higher than that found in maternal plasma (see section 5.3). There are no data on the effects of Gilenya on the breastfed child or the effects of Gilenya on milk production. Since many drugs are transferred into human milk and because of the potential for serious adverse reactions to fingolimod in nursing infants, females receiving Gilenya should not breastfeed.

Females and males of reproductive potential

Pregnancy testing

The pregnancy status of females of reproductive potential should be verified prior to starting treatment with Gilenya.

Contraception

Before initiation of Gilenya treatment, females of childbearing potential should be counselled regarding the potential for a serious risk to the foetus and the need for effective contraception during treatment with Gilenya and for 2 months after stopping treatment. Since it takes approximately two months to eliminate fingolimod from the body after stopping treatment (see section 4.4), the potential risk to the foetus may persist and contraception should be continued during this period.

Infertility

Data from preclinical studies do not suggest that fingolimod would be associated with an increased risk of reduced fertility (see section 5.3).

4.7 Effects on ability to drive and use machines

Gilenya has no or negligible influence on the ability to drive and use machines.

However, dizziness or drowsiness may occasionally occur when initiating therapy with Gilenya. On initiation of Gilenya treatment it is recommended that patients be observed for a period of 6 hours (see section 4.4, Bradycardia).

4.8 Adverse drug reactions

Summary of the safety profile

The safety population of Gilenya is derived from two Phase III placebo-controlled clinical trials and one Phase III active-controlled clinical trial in adult patients with relapsing remitting multiple sclerosis. It includes a total of 2,431 adult patients on Gilenya (0.5 or 1.25 mg dose). Study D2301 (FREEDOMS) was a 2-year placebo-controlled clinical study in 854 multiple sclerosis adult patients treated with fingolimod (placebo: 418). Study D2309 (FREEDOMS II) was a 2 year placebo-controlled clinical study in 728 multiple sclerosis adult patients treated with fingolimod (placebo: 355). In the pooled data from these two studies the most serious adverse drug reactions (ADRs) for the 0.5 mg recommended therapeutic dose were infections, macular oedema and transient atrioventricular block at treatment initiation. The most frequent ADRs (incidence $\geq 10\%$) at the 0.5 mg were headache, hepatic enzyme increased, diarrhoea, cough, influenza, sinusitis, and back pain. The most frequent adverse event reported for Gilenya 0.5 mg leading to treatment interruption was ALT elevations (2.2%).

The ADRs for fingolimod in Study D2302 (TRANSFORMS), a 1-year study in 849 adult patients treated with fingolimod which used interferon beta-1a as comparator, were generally similar to placebo-controlled studies, taking into account the differences in study duration.

Tabulated summary of adverse drug reactions from clinical trials

Table 1 presents the frequency of ADRs reported in the pooled analysis of the placebo-controlled studies FREEDOMS and FREEDOMS II. The ADRs were defined based on a difference of incidence (1% higher in active group over placebo) and/or medical assessment of each event.

ADRs are listed according to MedDRA system organ class. Frequencies were defined as follows: very common ($\geq 1/10$); common ($\geq 1/100$ to $< 1/10$); uncommon ($\geq 1/1,000$ to $< 1/100$); rare ($\geq 1/10,000$ to $< 1/1,000$); very rare ($< 1/10,000$); not known (cannot be estimated from the available data).

Table 1 Percentage of patients with adverse drug reactions in clinical trials

Adverse drug reactions	Fingolimod 0.5mg N=783 %	Placebo N=773 %	Frequency range for the 0.5 mg dose
Infections and infestations			
Influenza	11.4	8.4	very common
Sinusitis	10.9	8.3	very common

Adverse drug reactions	Fingolimod 0.5mg N=783 %	Placebo N=773 %	Frequency range for the 0.5 mg dose
Bronchitis	8.2	4.5	common
Herpes zoster	2.0	0.9	common
Tinea versicolor	1.8	0.4	common
Pneumonia	0.9	0.1	uncommon
Neoplasms benign, malignant and unspecified (incl cysts and polyps)			
Basal cell carcinoma	1.8	0.6	common
Melanoma	0.1	0.3	uncommon**
Kaposi's sarcoma	0	0	very rare**
Blood and lymphatic system disorders			
Lymphopenia	6.8	0.3	common
Leucopenia	2.2	0.1	common
Thrombocytopenia	0.5	0	uncommon
Nervous system disorders			
Headache	24.5	22.6	very common
Dizziness	8.8	8.4	common
Migraine	5.7	3.6	common
Seizure	0.9	0.3	uncommon
Posterior reversible encephalopathy syndrome (PRES)	0.0	0.0	rare*
Eye disorders			
Vision blurred	4.2	2.5	common
Macular edema	0.5	0.4	uncommon
Cardiac Disorders			
Bradycardia	2.6	0.9	common
Vascular disorders			
Hypertension	8.0	3.6	common
Respiratory, thoracic and mediastinal disorders			
Cough	12.3	11.3	very common
Dyspnoea	9.1	7.0	common
Gastrointestinal disorders			
Diarrhea	12.6	9.6	very common
Skin and subcutaneous tissue disorders			
Eczema	2.7	1.9	common
Pruritus	2.7	2.2	common
Musculoskeletal and connective tissue disorders			
Back pain	10.0	8.9	very common
General disorders and administration site conditions			
Asthenia	1.9	0.8	common
Investigations			
Hepatic enzyme increased (increased ALT, GGT, AST)	15.2	4.1	very common
Blood triglycerides increased	2.0	0.9	common

*Not reported in Study FREEDOMS, FREEDOMS II and TRANSFORMS. The frequency category was based on an estimated exposure of approximately 10, 000 patients to fingolimod in all clinical trials.

**The frequency category and risk assessment were based on an estimated exposure of more than 24,000 patients to fingolimod 0.5 mg in all clinical trials.

Adverse drug reactions from spontaneous reports and literature cases (frequency not known) The adverse drug reactions as listed in Table 2 have been derived from post-marketing experience with Gilenya via spontaneous case reports and literature cases. Because these reactions are reported voluntarily from a population of uncertain size, it is not possible to reliably estimate their frequency which is therefore categorized as not known. Adverse drug reactions are listed according to system organ classes in MedDRA.

Table 2 Adverse drug reactions from spontaneous reports and literature (frequency not known)

<p>Immune system disorders Hypersensitivity reactions, including rash, urticarial and angioedema upon treatment initiation</p> <p>Nervous system disorders Severe exacerbation of disease after Gilenya discontinuation (see section 4.4 Special warnings and precautions for use)</p> <p>Gastrointestinal disorders Nausea</p> <p>Musculoskeletal and connective tissue disorders Myalgia, arthralgia</p> <p>Investigations Weight decreased</p>
--

Description of selected adverse reactions

Infections

In multiple sclerosis clinical studies the overall rate of infections (65.1%) at the 0.5 mg dose was similar to placebo. However, bronchitis, herpes zoster and, to a lesser extent, pneumonia were more common in Gilenya-treated patients. Serious infections occurred at a rate of 1.6% in the fingolimod 0.5 mg group versus 1.4% in the placebo group.

There have been very rare fatal cases of VZV infections in the context of prolonged concomitant corticosteroid use (more than 5 days) for treatment of multiple sclerosis relapses, however, a causal relationship between the concomitant treatment and fatal outcome has not been established. Co-administration of a short course of corticosteroids (up to 5 days as per study protocols) did not increase the overall rate of infection in patients treated with fingolimod in the Phase III clinical trials, compared to placebo (see sections 4.4 and 4.5).

There have been very rare cases of other herpes viral infections with fatal outcome. However, a causal relationship with Gilenya has not been established.

Human papilloma virus (HPV) infection, including papilloma, dysplasia, warts and HPV-related cancer, has been reported under treatment with Gilenya in the post-marketing setting (see section 4.4).

In the post-marketing setting cases of infections with opportunistic pathogens, such as viral (e.g. VZV, JCV causing PML, HSV), fungal (e.g. cryptococci including cryptococcal meningitis) or bacterial (e.g. atypical mycobacterium), have been reported some of which have been fatal (see section Special Warnings and precautions for use).

Macular edema

In multiple sclerosis clinical studies macular oedema occurred in 0.5% of patients treated with the recommended dose of 0.5 mg and 1.1% of patients treated with the higher dose of 1.25 mg. The majority of cases occurred within the first 3-4 months of therapy. Some patients presented with blurred vision or decreased visual acuity, but others were asymptomatic and diagnosed on routine ophthalmic examination. The macular oedema generally improved or resolved spontaneously after discontinuation of Gilenya. The risk of recurrence after re-challenge has not been evaluated.

Macular oedema incidence is increased in multiple sclerosis patients with a history of uveitis (17% with a history of uveitis vs. 0.6% without a history of uveitis). Gilenya has not been studied in multiple sclerosis patients with diabetes mellitus, a disease which is associated with an increased risk for macular oedema (see section 4.4). In renal transplant clinical studies in which patients with diabetes mellitus were included, therapy with fingolimod 2.5 mg and 5 mg resulted in a 2-fold increase in the incidence of macular oedema.

Bradycardia

Initiation of Gilenya treatment results in a transient decrease in heart rate and may also be associated with atrioventricular conduction delays (see sections 4.4 and 5.1). In multiple sclerosis clinical studies the maximal decline in heart rate was seen within 6 hours after treatment initiation, with declines in mean heart rate of 12-13 beats per minute for Gilenya 0.5 mg. Heart rate below 40 beats per minute in adults, and below 50 bpm in paediatric patients, was rarely observed in patients on Gilenya 0.5 mg. Heart rate returned to baseline within 1 month of chronic treatment. Bradycardia was generally asymptomatic but some patients experienced mild to moderate symptoms, including hypotension, dizziness, fatigue and/or palpitations, which resolved within the first 24 hours after treatment initiation.

In multiple sclerosis clinical studies first-degree atrioventricular block (prolonged PR interval on ECG) was detected after treatment initiation in 4.7% of patients on fingolimod 0.5 mg, in 2.8% of patients on intramuscular interferon beta-1a, and in 1.6% of patients on placebo. Second-degree atrioventricular block was detected in less than 0.2% of adult patients on Gilenya 0.5 mg. In the post-marketing setting, isolated reports of transient, spontaneously resolving complete AV block have been observed during the six hour monitoring period following first dose of Gilenya. The patients recovered spontaneously. The conduction abnormalities observed both in clinical trials and post-marketing were typically transient, asymptomatic and resolved within the first 24 hours after treatment initiation. Although most patients did not require medical intervention, one patient on Gilenya 0.5 mg received isoprenaline for asymptomatic second-degree Mobitz I atrioventricular block.

In the post-marketing setting, isolated delayed onset events, including transient asystole and unexplained death, have occurred within 24 hours of the first dose. These cases have been confounded by concomitant medicinal products and/or pre-existing disease. The relationship of such events to Gilenya is uncertain.

Blood pressure

In multiple sclerosis clinical studies Gilenya 0.5 mg was associated with an average increase of approximately 3 mmHg in systolic pressure and approximately 1 mmHg in diastolic pressure, manifesting approximately 1 month after treatment initiation. This increase persisted with continued treatment. Hypertension was reported in 6.5% of patients on fingolimod 0.5 mg and in 3.3% of patients on placebo. In the post-marketing setting, cases of hypertension have been reported within the first month of treatment initiation and on the first day of treatment that may require treatment with antihypertensive agents or discontinuation of Gilenya (see also section 4.4, Blood pressure effects).

Liver function

Increased hepatic enzymes (mostly ALT elevation) have been reported in multiple sclerosis patients treated with Gilenya. In clinical studies 8.0% and 1.8% of patients treated with Gilenya 0.5 mg experienced an asymptomatic elevation in serum levels of ALT of $\geq 3x$ ULN (upper limit of normal) and $\geq 5x$ ULN, respectively. Recurrence of liver transaminase elevations has occurred upon re-challenge in some patients, supporting a relationship to the medicinal product. In clinical studies, ALT elevations occurred at any time during treatment although the majority occurred within the first 12 months. ALT levels returned to normal within approximately 2 months after discontinuation of Gilenya. In a small number of patients (N=10 on 1.25 mg, N=2 on 0.5 mg) who experienced ALT elevations of $\geq 5x$ ULN and who continued on Gilenya therapy, the ALT levels returned to normal within approximately 5 months (see also section 4.4, Liver function).

Nervous system disorders

Rare events involving the nervous system which occurred in patients treated with fingolimod at higher doses (1.25 or 5.0 mg) include ischaemic and haemorrhagic strokes and posterior reversible encephalopathy syndrome. Neurological atypical disorders have also been reported, such as acute disseminated encephalomyelitis (ADEM)-like events.

Seizures

Cases of seizures, including status epilepticus, have been reported with the use of Gilenya in clinical trials and in the post-marketing setting. It is unknown whether these events were related to the effects of multiple sclerosis alone, to Gilenya, or to a combination of both.

Description of safety aspects of special interest

Vascular disorders

In Phase III clinical trials rare cases of peripheral arterial occlusive disease occurred in patients treated with Gilenya at higher doses (1.25 mg). Rare cases of ischemic and hemorrhagic strokes have also been reported at the 0.5 mg dose in clinical trials and in the post-marketing setting although a causal relationship has not been established.

Respiratory system

Minor dose-dependent reductions in values for forced expiratory volume (FEV₁) and diffusion capacity for carbon monoxide (DLCO) were observed with Gilenya treatment starting at Month 1 and remaining stable thereafter. At Month 24, the reduction from baseline values in percentage of predicted FEV₁ was 2.7% for fingolimod 0.5 mg and 1.2% for placebo, a difference that resolved after treatment discontinuation. For DLCO the reductions at Month 24 were 3.3% for fingolimod 0.5 mg and 2.7% for placebo.

Lymphomas

There have been cases of lymphoma including Epstein-Barr virus (EBV) positive B-cell lymphoma in clinical studies and the post-marketing setting. The cases reported were heterogeneous in nature, mainly Non-Hodgkin's Lymphoma, including B-cell and T-cell lymphomas. Cases of cutaneous T cell lymphoma (mycosis fungoides) have been observed.

Special populations

Paediatric patients (10 years of age and above)

In the controlled paediatric trial, the safety profile in paediatric patients (10 to below 18 years of age) receiving Gilenya 0.25 mg or 0.5 mg daily was similar to that seen in adult patients.

In the paediatric study, cases of seizures were reported in 5.6% of fingolimod-treated patients and 0.9% of interferon beta-1a treated patients.

4.9 Overdose

No cases of overdose have been reported. However, single doses up to 80 times the recommended dose (0.5 mg) were well tolerated in healthy adult volunteers. At 40 mg, 5 of 6 subjects reported mild chest tightness or discomfort which was clinically consistent with small airway reactivity.

Fingolimod can induce bradycardia upon treatment initiation. The decline in heart rate usually starts within one hour of the first dose, and is steepest within 6 hours. The negative chronotropic effect of Gilenya persists beyond 6 hours and progressively attenuates over subsequent days of treatment (see section 4.4 for details). There have been reports of slow atrioventricular conduction, with isolated reports of transient, spontaneously resolving complete AV block (see sections 4.4 and 4.8).

If the overdose constitutes first exposure to Gilenya, it is important to monitor patients with a continuous (real time) ECG and hourly measurement of heart rate and blood pressure, at least during the first 6 hours (see section 4.4).

The occurrence at any time of third degree AV block should also lead to extended monitoring including overnight monitoring.

Neither dialysis nor plasma exchange results in removal of fingolimod from the body.

5. PHARMACOLOGICAL PROPERTIES

5.1 Pharmacodynamic properties

Pharmacotherapeutic group: Selective immunosuppressants, ATC code: L04AA27 Mechanism of action
Fingolimod is a sphingosine 1-phosphate receptor modulator. Fingolimod is metabolised by sphingosine kinase to the active metabolite fingolimod phosphate. Fingolimod phosphate binds at low nanomolar concentrations to sphingosine 1-phosphate (S1P) receptor 1 located on lymphocytes, and readily crosses the blood-brain barrier to bind to S1P receptor 1 located on neural cells in the central nervous system (CNS). By acting as a functional antagonist of S1P receptors on lymphocytes, fingolimod phosphate blocks the capacity of lymphocytes to egress from lymph nodes, causing a redistribution, rather than depletion, of lymphocytes. This redistribution reduces the infiltration of pathogenic lymphocytes, including pro-

inflammatory Th17 cells into the CNS, where they would be involved in nerve inflammation and nervous tissue damage. Animal studies and *in vitro* experiments indicate that fingolimod may also act via interaction with S1P receptors on neural cells. Fingolimod penetrates the CNS, in both humans and animals, and has been shown to reduce astrogliosis, demyelination and neuronal loss. Further, fingolimod treatment increases the levels of brain derived neurotrophic factor (BDNF) in the cortex, hippocampus and striatum of the brain to support neuronal survival and improve motor functions.

Pharmacodynamic effects

Within 4-6 hours after the first dose of fingolimod 0.5 mg, the lymphocyte count decreases to approximately 75% of baseline in peripheral blood. With continued daily dosing, the lymphocyte count continues to decrease over a two-week period, reaching a minimal count of approximately 500 cells/microlitre or approximately 30% of baseline. Eighteen percent of patients reached a minimal count below 200 cells/microlitre on at least one occasion. Low lymphocyte counts are maintained with chronic daily dosing. The majority of T and B lymphocytes regularly traffic through lymphoid organs and these are the cells mainly affected by fingolimod. Approximately 15-20% of T lymphocytes have an effector memory phenotype, cells that are important for peripheral immune surveillance. Since this lymphocyte subset typically does not traffic to lymphoid organs it is not affected by fingolimod. Peripheral lymphocyte count increases are evident within days of stopping fingolimod treatment and typically normal counts are reached within one to two months. Chronic fingolimod dosing leads to a mild decrease in the neutrophil count to approximately 80% of baseline. Monocytes are unaffected by fingolimod.

Fingolimod causes a transient reduction in heart rate and decrease in atrioventricular conduction at treatment initiation (see sections 4.4 and 4.8). The maximal decline in heart rate is seen within 6 hours post dose, with 70% of the negative chronotropic effect achieved on the first day. With continued administration heart rate returns to baseline within one month. The decrease in heart rate induced by fingolimod can be reversed by parenteral doses of atropine or isoprenaline. Inhaled salmeterol has also been shown to have a modest positive chronotropic effect. With initiation of fingolimod treatment there is an increase in atrial premature contractions, but there is no increased rate of atrial fibrillation/flutter or ventricular arrhythmias or ectopy. Fingolimod treatment is not associated with a decrease in cardiac output. Autonomic responses of the heart, including diurnal variation of heart rate and response to exercise are not affected by fingolimod treatment.

Fingolimod treatment with single or multiple doses of 0.5 and 1.25 mg for two weeks is not associated with a detectable increase in airway resistance as measured by FEV₁ and forced expiratory flow rate (FEF)₂₅₋₇₅. However, single fingolimod doses ≥ 5 mg (10-fold the recommended dose) are associated with a dose-dependent increase in airway resistance. Fingolimod treatment with multiple doses of 0.5, 1.25, or 5 mg is not associated with impaired oxygenation or oxygen desaturation with exercise or an increase in airway responsiveness to methacholine. Subjects on fingolimod treatment have a normal bronchodilator response to inhaled beta-agonists.

Clinical efficacy and safety

The efficacy of Gilenya has been demonstrated in two studies that evaluated once-daily doses of fingolimod 0.5 mg and 1.25 mg in adult patients with relapsing-remitting multiple sclerosis (RRMS). Both studies included patients who had experienced ≥ 2 relapses in the prior 2 years or ≥ 1 relapse during the prior year. Expanded Disability Status Score (EDSS) was between 0 and 5.5. A third study targeting the same patient population was completed after registration of Gilenya.

The efficacy and safety of once-daily doses of Gilenya 0.25 mg or 0.5 mg (dose selected based on body weight and exposure measurements) have been established in paediatric patients aged 10 to <18 years old with relapsing-remitting multiple sclerosis.

Study D2301 (FREEDOMS)

Study D2301 (FREEDOMS) was a 2-year randomised, double-blind, placebo-controlled Phase III study of 1,272 patients (n=425 on 0.5 mg, 429 on 1.25 mg, 418 on placebo). Median values for baseline characteristics were: age 37 years, disease duration 6.7 years, and EDSS score 2.0. Outcome results are shown in Table 3 and Figures 1 and 2. There were no significant differences between the 0.5 mg and the 1.25 mg doses as regards either endpoint.

Table 3 Clinical and MRI results of Study FREEDOMS

	Gilenya 0.5 mg	Gilenya 1.25 mg	Placebo
Clinical endpoints	N=425	N=429	N=418

All analyses of clinical endpoints were intent-to treat. MRI analyses used the evaluable dataset.

* Indicates statistical significance vs. placebo at two-sided 0.05 level.

Determination of p-values: aggregate ARR by negative binomial regression adjusting for treatment, pooled country, number of relapses in previous 2 years and baseline EDSS; percentage of patients maintaining relapse-free logistic regression adjusted for treatment, country, number of relapses in previous 2 years, and baseline EDSS; time to 3-month/6-month confirmed disability progression by Cox's proportional hazards model adjusted for treatment, pooled country, baseline EDSS, and age; new/newly enlarging T2 lesions by negative binomial regression adjusted for treatment and pooled country; Gd-enhancing lesions by rank ANCOVA adjusted for treatment, pooled country, and baseline number of Gd-enhancing lesions; and % change in lesion and brain volume by rank ANCOVA adjusted for treatment, pooled country, and corresponding baseline value.

Figure 1 Kaplan-Meier plot of time to first confirmed relapse up to Month 24 – Study FREEDOMS (ITT population)

Figure 2 Cumulative plot of time to 3-month confirmed disability progression – Study FREEDOMS (ITT population)

Patients who completed Study FREEDOMS (D2301) had the option to enter a dose-blinded extension study D2301E1. 920 patients from the core study entered the extension and were all treated with fingolimod (n=331 continued on 0.5 mg, 289 continued on 1.25 mg, 155 switched from placebo to 0.5 mg and 145 switched from placebo to 1.25 mg). 811 of these patients (88.2%) had at least 18 months follow-up in the extension phase. The maximum cumulative duration of exposure to fingolimod 0.5 mg (core + extension study) was 1,782 days.

At Month 24 of the extension study, patients who received placebo in the core study had reductions in ARR of 55% after switching to fingolimod 0.5 mg (ARR ratio 0.45, 95% CI 0.32 to 0.62, $p < 0.001$). The ARR for patients who were treated with fingolimod 0.5 mg in the core study remained low during the extension study (ARR of 0.10 in the extension study).

Study D2309 (FREEDOMS II)

Study D2309 (FREEDOMS II) had a design similar to that of Study D2301 (FREEDOMS): it was a 2- year randomized, double-blind, placebo-controlled Phase III study in patients with relapsing-remitting multiple sclerosis who had not received any interferon-beta or glatiramer acetate for at least the previous 3 months and had not received any natalizumab for at least the previous 6 months. Neurological evaluations were performed at screening, every 3 months and at time of suspected relapse. MRI evaluations were performed at screening, Month 6, Month 12 and Month 24. The primary endpoint was the annualized relapse rate (ARR).

Median age was 40.5 years, median disease duration was 8.9 years and median EDSS score at baseline was 2.5. Patients were randomized to receive Gilenya 0.5 mg (n=358) or Gilenya 1.25 mg (n=370), or placebo (n=355) for up to 24 months.

Median time on study drug was 719 days on 0.5 mg and 719 days on placebo. Patients randomized to the fingolimod 1.25 mg dose arm were switched in a blinded manner to receive fingolimod 0.5 mg when results of Study 2301 became available and confirmed a better benefit/risk profile of the lower dose. The dose was switched in 113 patients (30.5%) in this dose arm, median time on fingolimod 1.25 mg in this arm was 496.1 days and 209.8 days on fingolimod 0.5 mg.

The annualized relapse rate was significantly lower in patients treated with Gilenya than in patients who received placebo. The first key secondary endpoint was change from baseline in brain volume. Loss of brain volume was significantly less with Gilenya treatment compared to placebo. The other key secondary endpoint was the time to 3-month confirmed disability progression as measured by at least a 1-point increase from baseline in EDSS (0.5 point increase for patients with baseline EDSS of 5.5) sustained for 3 months. The risk of disability progression for Gilenya and placebo groups was not statistically different.

There were no significant differences between the 0.5 mg and the 1.25 mg doses on any of the endpoints.

The results for this study are shown in Table 4 and Figure 3.

Table 4 Clinical and MRI results of Study FREEDOMS II

	Gilenya 0.5 mg	Gilenya 1.25 mg	Placebo

Percent change in T2 lesion total volume	n=262	n= 242	n=247
Median (mean) % change over 24 months	-7.1 (13.7) (p<0.001*)	-10.1 (-7.7) (p<0.001*)	0.8 (25.1)
Change in T1 hypointense lesion volume	n=225	n=209	n=209
Median (mean) % change over 24 months	-9.9 (12.6) (p=0.372)	-10.9 (-4.7) (p=0.205)	-8.5 (26.4.)

All analyses of clinical endpoints were intent-to treat. MRI analyses used the evaluable dataset.

* Indicates statistical significance vs. placebo at two-sided 0.05 level.

Determination of p-values: aggregate ARR by negative binomial regression adjusted for treatment, pooled country, number of relapses in previous 2 years and baseline EDSS; percentage of patients maintaining relapse-free logistic regression adjusted for treatment, country, number of relapses in previous 2 years, and baseline EDSS; time to 3-month/6-month confirmed disability progression by Cox's proportional hazards model adjusted for treatment, pooled country, baseline EDSS, and age; new/newly enlarging T2 lesions by negative binomial regression adjusted for treatment and pooled country; Gd-enhancing lesions by rank ANCOVA adjusted for treatment, pooled country, and baseline number of Gd-enhancing lesions; and % change in lesion and brain volume by rank ANCOVA adjusted for treatment, pooled country, and corresponding baseline value.

† Additional analyses revealed that results in the overall population were not significant due to false positive progressions in the subgroup of patients with baseline EDSS=0 (n=62, 8.7% of study population). In patients with EDSS>0 (n=651; 91.3% of study population), fingolimod 0.5 mg demonstrated a statistically significant reduction compared to placebo (HR= 0.70; CI (0.50, 0.98); p=0.040) for the 3-month disability progression, consistent with study FREEDOMS

Figure 3 Kaplan-Meier plot of time to first confirmed relapse up to Month 24 – Study FREEDOMS II (ITT population)

Study D2302 (TRANSFORMS)

Study D2302 (TRANSFORMS) was a 1-year randomised, double-blind, double-dummy, active-controlled (interferon beta-1a) Phase III study of 1,280 patients (n=429 on 0.5 mg, 420 on 1.25 mg, 431 on interferon beta-1a, 30 µg by intramuscular injection once weekly). Median values for baseline characteristics were: age 36 years, disease duration 5.9 years, and EDSS score 2.0. Outcome results are shown in Table 5 and Figure 4. There were no significant differences between the Gilenya 0.5 mg and the 1.25 mg doses as regards study endpoints.

Table 5 Clinical and MRI results of Study TRANSFORMS

	Gilenya 0.5 mg	Gilenya 1.25 mg	Interferon beta-1a IM, 30 mcg,
Clinical endpoints	N=429	N=420	N=431
Annualized relapse rate (primary endpoint)	0.16 (p<0.001*)	0.20 (p<0.001*)	0.33
Relative reduction (percent)	52	38	
Percent of patients remaining relapse-free at 12 months	82.5 (p<0.001*)	80.5 (p<0.001*)	70.1
Risk of disability progression			
Hazard ratio (95% CI) (3-month confirmed)	0.71 (0.42, 1.21) (p=0.209)	0.85 (0.51, 1.42) (p=0.543)

Determination of p-values: aggregate ARR by negative binomial regression adjusting for treatment, country, number of relapses in previous 2 years and baseline EDSS; percentage of patients maintaining relapse-free logistic regression adjusted for treatment, country, number of relapses in previous 2 years, and baseline EDSS; risk of disability progression by Cox's proportional hazards model adjusted for treatment, country, baseline EDSS, and age; new/newly enlarging T2 lesions by negative binomial regression adjusted for treatment, country, number of relapses in previous 2 years and baseline EDSS; Gd-enhancing lesions by rank ANCOVA adjusted for treatment, country, and baseline number of Gd-enhancing lesions; and % change in brain volume by Wilcoxon rank sum test.

Figure 4 Kaplan-Meier plot for time to first confirmed relapse up to Month 12 – Study TRANSFORMS (ITT population)

Patients who completed Study TRANSFORMS (D2302) had the option to enter a dose-blinded extension. 1,030 patients from the core study entered the extension (Study D2302E1) and were treated with fingolimod (n=357 continued on 0.5 mg, 330 continued on 1.25 mg, 167 switched from interferon beta-1a to 0.5 mg and 176 switched from interferon beta-1a to 1.25 mg). 882 of these patients (85.9%) had at least 12 months follow-up in the extension phase. The maximum cumulative duration of exposure to fingolimod 0.5 mg (core + extension study) was 1,594 days.

At Month 12 of the extension study, patients who received interferon beta-1a i.m. in the core study had relative reductions in ARR of 30% after switching to fingolimod 0.5 mg (ARR ratio=0.70, p=0.06). The ARR for patients who were treated with fingolimod 0.5 mg in the core study was low during the combined core and extension study (ARR of 0.18 up to Month 24).

Pooled results of Studies D2301 (FREEDOMS) and D2302 (TRANSFORMS) showed a consistent and statistically significant reduction in annualised relapse rate with Gilenya compared to comparator in subgroups defined by gender, age, prior multiple sclerosis therapy, disease activity or disability levels at baseline.

Further analyses of clinical trial data demonstrate consistent treatment effects in highly active subgroups of relapsing remitting multiple sclerosis patients.

Study D2311 (PARADIGMS) in paediatric patients 10 years of age and above

Study D2311 (PARADIGMS) was a double-blind, randomized, active-controlled, parallel-group, multicenter study with flexible duration up to 24 months, to evaluate the efficacy and safety of fingolimod compared to interferon beta-1a in paediatric patients with MS, aged 10 to <18 years old. Prior therapy with interferon-beta, dimethyl fumarate or glatiramer acetate up to the time of randomization was permitted. Neurological evaluations were performed at screening, every 3 months and at the time of suspected relapses. MRI evaluations were performed at screening, and every 6 months throughout the study. The

primary endpoint was the annualized relapse rate.

Median age was 16 years, median disease duration since first symptom was 1.5 years and median EDSS score at baseline was 1.5. Patients were randomized to receive fingolimod or interferon beta-1a via the intramuscular route once weekly for up to 24 months. Median time on study drug was 634 days on fingolimod and 547 days on interferon beta-1a.

The primary endpoint, the annualized relapse rate, was significantly lower in patients treated with fingolimod than in patients who received interferon beta-1a (relative reduction in ARR of 81.9%). The key secondary endpoint, the annualized rate of the number of new or newly enlarged T2 lesions up to Month 24, was also significantly lower in patients treated with fingolimod than in patients who received interferon beta-1a, as was the number of Gd-enhancing T1 lesions per scan up to Month 24. Fingolimod also significantly reduced the annualized rate of brain atrophy from baseline up to Month 24. An additional post-hoc analysis confirmed that time to onset of 3-month confirmed disability progression was significantly delayed with fingolimod compared to interferon beta-1a.

The results for this study are shown in Table 6, Figure 5, and Figure 6.

Table 6 Clinical and MRI results of Study PARADIGMS

	Fingolimod 0.25 mg or 0.5 mg	Interferon beta-1a IM 30 µg
Clinical endpoints	N=107	N=107 [#]
Annualized relapse rate (primary endpoint)	0.122 (p<0.001*)	0.675
Relative reduction (percent)	81.9	
Percent of patients remaining relapse-free at 24 months	85.7 (p<0.001*)	38.8
Risk of disability progression		
Hazard ratio (95% CI)	0.23 (0.08,0.66)	
	Fingolimod 0.25 mg or 0.5 mg	Interferon beta-1a IM 30 µg
(3-month confirmed)	(p=0.007*)	
MRI endpoints		
Annualized rate of the number of new or newly enlarging T2 lesions	n=106	n=102
Adjusted mean	4.393 (p<0.001*)	9.269
Relative Reduction (percent)	52.6	
Number of Gd-enhancing T1 lesions per scan up to Month 24	n=105	n=95
Adjusted mean	0.436 (p<0.001*)	1.282
Relative Reduction (percent)	66.0	
Annualized rate of brain atrophy from baseline up to Month 24	n=96	n=89
Least Square Mean	-0.48 (p=0.014*)	-0.80

All analyses of clinical endpoints were on full analysis set. MRI analyses used the evaluable dataset.

[#] One patient was randomized to receive Interferon beta-1a IM, 30 µg weekly, but was unable to swallow the double dummy medication and discontinued from the study. This patient was excluded from the full analysis and safety set.

* Indicates statistical significance vs. Interferon beta-1a IM at two-sided 0.05 level.

Determination of p-values: aggregate ARR by negative binomial regression adjusting for treatment, region, pubertal status (the stratification factor in interactive voice response system, IVRS), and the number of relapse in the last 2 years (offset: time in study); percentage of patients maintaining relapse-free based on Kaplan-Meier estimate; risk of disability progression by Cox's proportional hazards model adjusted for treatment, region, pubertal status (the stratification factor in IVRS), and the number of relapse in the last 2 years; Annualized rate of number of new/newly enlarging T2 lesions by negative binomial regression adjusted for treatment, region, pubertal status (the stratification factor in IVRS), and baseline T2 lesion number (offset: time in study); Number of Gd- enhancing lesions per scan by a negative binomial

regression with the cumulative number of T1 Gd- enhancing lesions on all scheduled post-baseline MRI scans during the study as the response variable adjusted for treatment, region, pubertal status (the stratification factor in IVRS), and baseline number of T1 Gd-enhancing lesions (offset: number of MRI scans); and annualized rate of brain atrophy by an ANCOVA model adjusted for treatment, region, pubertal status (the stratification factor in IVRS), and baseline whole brain volume.

Figure 6 Kaplan-Meier plot of time to 3-month confirmed disability progression – Study PARADIGMS (Full analysis set)

5.2 Pharmacokinetic properties

Pharmacokinetic data were obtained in healthy volunteers, in renal transplant patients and in multiple sclerosis patients.

The pharmacologically active metabolite responsible for efficacy is fingolimod phosphate.

Absorption

Fingolimod absorption is slow (t_{max} of 12-16 hours) and extensive ($\geq 85\%$). The apparent absolute oral bioavailability is 93% (95% confidence interval: 79-111%). Steady-state-blood concentrations are reached within 1 to 2 months of once-daily administration and steady-state levels are approximately 10-fold greater than with the initial dose.

Food intake does not alter C_{max} or exposure (AUC) of fingolimod. Fingolimod phosphate C_{max} was slightly increased by 34% but AUC was unchanged. Therefore, Gilenya may be taken without regard to meals (see section 4.2).

Distribution

Fingolimod highly distributes in red blood cells, with the fraction in blood cells of 86%. Fingolimod phosphate has a smaller uptake in blood cells of <17%. Fingolimod and fingolimod phosphate are highly protein bound (>99%).

Fingolimod is extensively distributed to body tissues with a volume of distribution of about $1,200 \pm 260$ litres. A study in four healthy subjects who received a single intravenous dose of radioiodolabeled fingolimod demonstrated that fingolimod penetrates into the brain. In a study in 13 male multiple sclerosis patients who received Gilenya 0.5 mg/day at steady-state, the amount of fingolimod (and fingolimod-phosphate) in seminal ejaculate was more than 10,000 times lower than the dose administered (0.5 mg). Fingolimod semen concentrations were 1.47-fold (geometric mean) greater than those in blood.

Biotransformation

Fingolimod is transformed in humans by reversible stereoselective phosphorylation to the pharmacologically active (S)-enantiomer of fingolimod phosphate. Fingolimod is eliminated by oxidative biotransformation catalyzed mainly by CYP4F2 and possibly other CYP4F isoenzymes and subsequent fatty acid-like degradation to inactive metabolites, and by formation of pharmacologically inactive non-polar ceramide analogues of fingolimod. The main enzyme involved in the metabolism of fingolimod is partially identified and may be either CYP4F2 or CYP3A4.

Following single oral administration of [¹⁴C] fingolimod, the major fingolimod-related components in blood, as judged from their contribution to the AUC up to 34 days post dose of total radiolabelled components, are fingolimod itself (23%), fingolimod phosphate (10%), and inactive metabolites (M3 carboxylic acid metabolite (8%), M29 ceramide metabolite (9%) and M30 ceramide metabolite (7%)).

Elimination

Fingolimod blood clearance is 6.3±2.3 l/h, and the average apparent terminal elimination half-life ($t_{1/2}$) is 6-9 days. Blood levels of fingolimod and fingolimod phosphate decline in parallel in the terminal phase, leading to similar half-lives for both.

After oral administration, about 81% of the dose is slowly excreted in the urine as inactive metabolites. Fingolimod and fingolimod phosphate are not excreted intact in urine but are the major components in the faeces, with amounts representing less than 2.5% of the dose each. After 34 days, the recovery of the administered dose is 89%.

Linearity

Fingolimod and fingolimod phosphate concentrations increase in an apparently dose proportional manner after multiple once-daily doses of 0.5 mg or 1.25 mg.

In paediatric patients, fingolimod-phosphate concentrations increase in an apparent dose proportional manner after multiple once daily doses of fingolimod 0.25 mg or 0.5 mg.

Characteristics in specific groups of patients

The pharmacokinetics of fingolimod and fingolimod phosphate do not differ in males and females, in patients of different ethnic origin, or in patients with mild to severe renal impairment.

In subjects with mild, moderate, or severe hepatic impairment (Child-Pugh class A, B, and C), no change in fingolimod C_{max} was observed, but fingolimod AUC was increased respectively by 12%, 44%, and 103%. In patients with severe hepatic impairment (Child-Pugh class C), fingolimod-phosphate C_{max} was decreased by 22% and AUC increased by 38%. The pharmacokinetics of fingolimod-phosphate were not evaluated in patients with mild or moderate hepatic impairment. The apparent elimination half-life of fingolimod is unchanged in subjects with mild hepatic impairment, but is prolonged by about 50% in patients with moderate or severe hepatic impairment.

Fingolimod should not be used in patients with severe hepatic impairment (Child-Pugh class C) (see section 4.3). Fingolimod should be introduced cautiously in mild and moderate hepatic impaired patients (see section 4.2).

Clinical experience and pharmacokinetic information in patients aged above 65 years are limited. Gilenya should be used with caution in patients aged 65 years and over (see section 4.2).

Paediatric population

The median fingolimod-phosphate concentration in paediatric MS patients aged 10 to less than 18 years was 1.10 ng/mL, as compared to 1.35 ng/mL in adult MS patients.

There are limited data available from a renal transplant study that included 7 children above 11 years of age (study FTY720A0115). The comparison of these data to those in adult healthy volunteers is of limited

relevance and no valid conclusions can be drawn regarding the pharmacokinetic properties of fingolimod in children.

5.3 Preclinical safety data

The preclinical safety profile of fingolimod was assessed in mice, rats, dogs and monkeys. The major target organs were the lymphoid system (lymphopenia and lymphoid atrophy), lungs (increased weight, smooth muscle hypertrophy at the bronchio-alveolar junction), and heart (negative chronotropic effect, increase in blood pressure, perivascular changes and myocardial degeneration) in several species; blood vessels (vasculopathy) in rats only at doses of 0.15 mg/kg and higher in a 2-year study, representing an approximate 4-fold margin based on the human systemic exposure (AUC) at a daily dose of 0.5 mg.

No evidence of carcinogenicity was observed in a 2-year bioassay in rats at oral doses of fingolimod up to the maximum tolerated dose of 2.5 mg/kg, representing an approximate 50-fold margin based on human systemic exposure (AUC) at the 0.5 mg dose. However, in a 2-year mouse study, an increased incidence of malignant lymphoma was seen at doses of 0.25 mg/kg and higher, representing an approximate 6-fold margin based on human systemic exposure (AUC) at a daily dose of 0.5 mg.

Fingolimod was neither mutagenic nor clastogenic in animal studies.

Fingolimod had no effect on sperm count or motility or on fertility in male and female rats up to the highest dose tested (10 mg/kg), representing an approximate 150-fold margin based on human systemic exposure (AUC) at a daily dose of 0.5 mg.

Fingolimod was excreted in the milk of treated animals during lactation. Fingolimod and its metabolites crossed the placental barrier in pregnant rabbits.

Juvenile Animal Studies

In a study in which fingolimod (0.3, 1.5, or 7.5 mg/kg/day) was orally administered to young rats from weaning through sexual maturity, changes in bone mineral density and persistent neurobehavioral impairment (altered auditory startle) were observed at all doses. Delayed sexual maturation was noted in females at the highest dose tested and in males at all doses. The bone changes observed in fingolimod-treated juvenile rats are consistent with a reported role of S1P in the regulation of bone mineral homeostasis. When fingolimod (0.5 or 5 mg/kg/day) was orally administered to rats from the neonatal period through sexual maturity, a marked decrease in T-cell dependent antibody response was observed at both doses. This effect had not fully recovered by 6-8 weeks after the end of treatment. Overall, the no observed adverse effect levels (NOAELs) in juvenile animals were mainly driven by unspecific effects on body weight or food consumption.

Environmental Risk Assessment (ERA)

A risk for the environment due to use of Gilenya by patients with relapsing multiple sclerosis is not expected.

6. PHARMACEUTICAL PARTICULARS

6.1 List of excipients

Table 7: List of excipients

	Gilenya 0.5 mg capsule	Gilenya 0.25 mg capsule
Capsule core	Magnesium stearate Mannitol	Mannitol Hydroxypropylcellulose Hydroxypropylbetadex Magnesium stearate Water, purified
